SUMMARY

Cloud integration engineer who builds event-driven Azure systems connecting telephony, AI services, vendor APIs, and business platforms. Owns two production platforms end to end at a managed services provider — a call-automation pipeline spanning Azure Communication Services, Speech, and Azure OpenAI into Autotask, and a multi-vendor network monitor that reconciles detected issues into tickets automatically. Focused on idempotency, traceability, and safe AI output.

TECHNICAL SKILLS

Azure: Functions (Python), Communication Services, Event Grid, Speech, Azure OpenAI, AI Foundry, Blob & Table Storage, Static Web Apps, Logic Apps, Key Vault, Managed Identity, Application Insights, Cost Management API

Integration & APIs: REST API design, JSON schema validation, OAuth 2.0, webhooks, event-driven architecture, idempotency and correlation tracing, vendor API integration (Autotask, UniFi, SonicWall, Cisco Meraki, NVD/EPSS, Stripe)

Languages: Python, TypeScript, JavaScript, SQL

Practices & Tooling: Azure DevOps CI/CD, Git, pytest, KQL / Application Insights alerting, Key Vault secret management, React + Vite for operator tooling

PROFESSIONAL EXPERIENCE

E3 IT Services — Azure DevOps Engineer

2024 – Present · Managed IT services provider

Call Automation Platform — ACS → Speech → Azure OpenAI → Autotask

- Architected a production platform across three Python Azure Function Apps that answers inbound Azure Communication Services calls, routes them through an ordered Microsoft Teams engineer queue with automatic voicemail failover, records to Blob Storage, transcribes with Azure Speech batch jobs, and generates client-ready documentation with Azure OpenAI — posting the finished time entry to the engineer's active Autotask ticket with no manual step.
- Designed table-backed idempotency around every external side effect — Event Grid events, call connections, recording IDs, blob uploads, AI analyses, and Autotask posts — so at-least-once webhook delivery and retries cannot produce duplicate recordings, analyses, or ticket notes. Failed operations release their claim row so Event Grid redelivery retries safely.
- Built a sanitized correlation ID propagated across ten hops — ACS callbacks, Logic App notifications, Table partitions, blob metadata, Speech and Azure OpenAI client-request headers, and Autotask idempotency rows — making any call traceable end to end from a single KQL query in Application Insights.
- Hardened the AI layer against prompt injection: transcripts are wrapped as untrusted data and scrubbed of control characters, SAS URLs, connection strings, keys, and instruction-override phrases; output is constrained to a strict JSON schema and re-validated before any external write. Engineer identity comes from trusted Teams UID metadata, not model inference.
- Built a React 19 + TypeScript operations dashboard on Azure Static Web Apps with a Node API — service health, storage and table analytics, a searchable recording and transcript explorer with HTTP Range-based seekable audio, and Azure Cost Management integration reporting cost per call, with all secrets kept server-side.

Unified Network Monitor — UniFi / SonicWall / Cisco Meraki → Autotask

- Built a multi-vendor monitoring platform on timer-triggered Azure Functions that polls UniFi, SonicWall, and Cisco Meraki APIs every five minutes, normalizes vendor data into Blob snapshots, and reconciles detected issues into Autotask tickets through a Table Storage state machine that opens, touches, and auto-resolves tickets without duplicates.
- Wrote detection as pure, I/O-free Python modules covering site-down, WAN failover, latency, pending-firmware, firewall, VPN, license, and uplink rules, with alert-suppression hierarchies and unit tests across ten modules. Vendor runs returning inventory-only data skip reconciliation, so a partial API outage cannot auto-resolve live tickets.
- Added a daily advisory pipeline enriching vendor security advisories with NVD CVE detail and FIRST EPSS exploit-probability scores, matching them to deployed firmware and opening tickets automatically. Secrets resolve through Key Vault and managed identity.

P&S Ravioli Company — Full Stack Developer (Freelance)

2024

- Built a real-time inventory platform on Firestore with auto-generated UPC barcodes, multi-location stock tracking, and role-based dashboards for drivers and managers, cutting inventory lookup time by roughly 50%.

Dolce Vita Gelato — Full Stack Developer

2023 – 2024 · Live: gelato-system-demo.web.app

- Designed and built nine integrated systems on one shared real-time Firebase backend — mobile ordering with Stripe checkout and GPS geofenced arrival alerts, in-store kiosk, digital signage, order management, inventory, and role-gated staff tooling.

EDUCATION & CERTIFICATIONS

B.S. Computer Science, Networking Systems Concentration — Rowan University, May 2024

A.S. Computer Science — Rowan College of South Jersey, 2022
